ABSTRACT

The acute intramuscular toxicity of MMB-4 was determined in male ICR mice by using the single dose method. LD₁, LD₅₀, and LD₉₅ with their 95% confidence limits were calculated by probit analysis. The LD₅₀ was 448 mg/kg with the 95% confidence limit (398 mg/kg, 506 mg/kg). The MMB-4 formulation falls in the very toxic range.

SIGNATURES OF PRINCIPAL SCIENTISTS AND MANAGERS INVOLVED IN THE STUDY:

We, the undersigned, believe the study number d2009 described in this report to be scientifically sound and the results in this report and interpretation to be valid. The study was conducted to comply, to the best of our ability, with the Good Laboratory Practice Regulations outlined by the Food and Drug Administration.

Acute Intramuscular Toxicity (LD_{50}) of 1,1'-Methylenebis [4-[(Hydroxyimino) Methyl] Pyridinimium] Dibromide, (MMB-4) in Male Mice--White, Sauers and Hanes

One of the goals of the Army Chemical Warfare Defense Program is to develop effective therapeutic compounds for the treatment of specific organophosphate intoxication. Compounds of low toxicity are sought for use since high peripheral concentration (related to effective dose) are necessary. The high peripheral concentration allows for the passage of quaternary ammonium oxime compounds through the blood-brain barrier to achieve therapeutic concentration at specific cholinesterase reactivation sites (1-3).

Objective of the Study

The objective of this study was to determine the acute intramuscular toxicity potential of 1.1'-methylenebis [4-[(hydroxyimino) methyl] pyridinium] dibromide in male ICR mice.

METHODS

Animal data appear in Appendix B.

Environmental Conditions

Environmental conditions are described in Appendix C.

Dosing

A 25% weight/volume solution of MMB-4 in sterile water for injection (USP) was prepared between 0830-0845 on 7 April 1982.

Five dose levels (300 mg/kg, 400 mg/kg, 500 mg/kg, 600 mg/kg, and 700 mg/kg) were selected based upon the results of the Approximate Lethal Dose (ALD) Study which suggested a LD_{50} of between 400 mg/kg and 500 mg/kg. Information obtained from US Army Institute of Chemical Defense indicated an IM LD of 560 mg/kg (L. Harris, PhD, US Army Biomedical Laboratory, personal communication, 1982). The dose for each animal was calculated based on the animal's weight, the dose level desired, and the compound concentration in solution. level was increased by graded volumetric increases rather than varying compound solution concentration. The intramuscular administered ranged from 40 ul (0.040 ml) to 107 ul (0.107 ml). in the control group were untreated. A vehicle control group was not used due to the low toxicity of sterile water for injection (USP). The dosing material was injected into the caudal thigh muscle mass.

All animals were single dosed on 7 April 1982. Gas sterilized Hamilton gas-tight syringes (1705-LT) were used with sterile, disposable twenty-six gauge, one-half inch needles (Becton, Dickinson & Co.). The dosing procedures were conducted without animal sedation or anesthesia.

Observations

Animal observations were conducted and recorded daily commencing at 1400 hours. An additional observation period was conducted immediately following dosing. Animals were observed at 0700 hours on the day of sacrifice.

Statistical Methods

The LD , LD $_{50}$, LD $_{95}$ and slope determination were derived by Bliss probit analysis, as described by Finney (4).

Duration of Study

The study period was 14 days with a 7--day quarantine before the study onset.

Historical listing of study events appears in Appendix D.

Changes to Original Procedures

During dosing, Animal 154 (500 mg/kg dose group) did not receive the full calculated dose, and it was not included in the tabulation of the results.

RESULTS

THE PROPERTY OF THE PROPERTY O

Mortality

Table 1 lists the compound-related deaths by group and the percent mortality.

TABLE 1
Compound-Related Deaths by Group

| Group | Dose Level | Compound-Related Death: Number in Group | % Mortality |
|-------|--------------------|--|-------------|
| 1 | 300 mg/kg | 0/8 | 0% |
| 2 | 400 mg/kg | 2/8 | 25% |
| 3 | 500 mg/kg | 6/7* | 86\$ |

| 5 | 790 mg/kg | 8/8 | 100\$ |
| 6 | untreated controls | no mortality | |

^{*}One animal eliminated because of misdosing.

Lethal Dose Calculations

Lethal dose (LD) values calculated by probit analysis for MMB-4 are given below for male ICR mice (Table 2). Figure 1 represents the dose response relationship curve when plotted as percent mortality versus dosage used. Figure 2 represents the dose response relationship curve with 95% confidence limits added.

TABLE 2*
Lethal Dose (LD) Levels of MMB-4 in Male Mice

| Percent Population | Lethal Dose (mg/kg) | 95% Confidence Limits (mg/kg) |
|--------------------|------------------------|-------------------------------------|
| LD ₁ | 295 | (207, 420) |
| LD ₁₆ | 375 | (308, 456) |
| LD30 | 408 | (351, 475) |
| LD ₅₀ | 448 | (398, 506) |

^{*}Statistician's report (Appendix E)

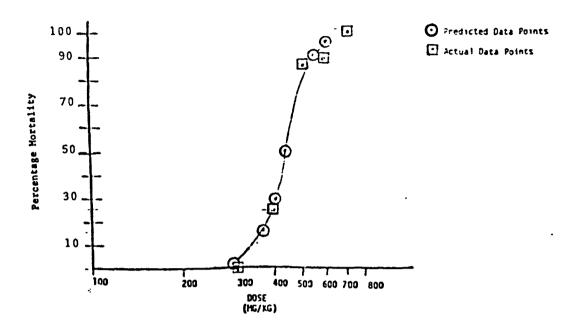

Figure 1: LD₅₀ for MMB-4, Probit Analysis Derived Dose Response Curve, Male ICR Mice.

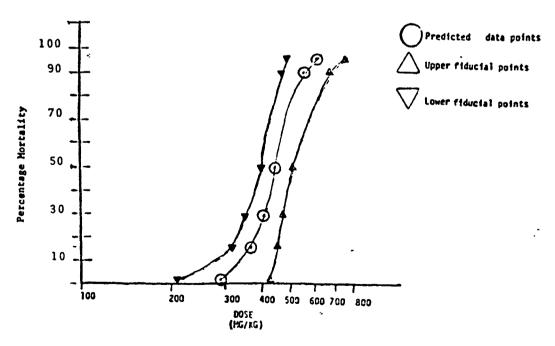

Figure 2: Lethal Dose for MMB-4, Probit Analysis Derived Response Confidence Limit Curve, Male ICR Mice.

Clinical Observations

Animals were observed daily, subsequent to dosing, undisturbed in cages, outside of cages and after placement in cages. On the day of dosing, the animals were observed intermittently throughout the entire dosing procedure. Animals which exhibited clinical signs (other than slight depression) died quickly after the onset of signs. Typically, the animals developing clinical signs would at first become depressed and inactive. Development of muscle tremors and ataxia would then be accompanied by an increase in the respiratory rate. Breathing would become very shallow. Animals lost equilibrium and ability to ambulate. Cyanosis, which accompanied the onset of increased respiratory rate, was followed closely by agonal convulsions lasting 15 to 35 seconds.

Clinical signs indicated that the toxicity observed was of the anticholinergic-type. From clinical observation, it is <u>reasonable</u> to conclude that death occurred as a result of the neuromuscular blockade effect of MMB-4.

Gross Pathological Observations

The veterinary pathologist's report appears in Appendix F.

DISCUSSION

The calculated LD $_{50}$ for MMB-4 in male ICR mice was 448 mg/kg with a 95% confidence limit of (398 mg/kg, 506 mg/kg). The LD $_{50}$ is within the very tox: range (5).

Clinical signs of toxicity included increased respiratory rate, decreased respiratory depth, depression, inactivity, ataxia, loss of equilibrium and gait, cyanosis, tremors, convulsions and death. All animals (except 166) which developed clinical signs, other than mild depression, disc during convulsions. Animal number 166 developed signs of intoxication but recovered to survive the observation period.

CONCLUSION

The LD_{50} for MMB-4 was determined to be 448 mg/kg in male ICR mice. The formulation is considered to be very toxic (5).

RECOMMENDATION

MMB-4 should be considered for further safety testing for eventual human use, provided the efficacy is verified.

HISTORICAL LISTING OF STUDY EVENTS

| 30 Mar 82 | 50 male ICR mice were received at LAIR. Mice were housed in groups of 3 to 5 and tagged on the skin between and above the shoulder. Animals were weighed and 2 animals were submitted for quality control necropsy. |
|----------------------|---|
| 2 Apr 82 | Animals were randomized, weighed, dosed and observed immediately. Animals that died were submitted for gross necropsy. |
| 8 - 21 | All animals were observed daily for clinical signs. |
| 9,12,15,19,21 Apr 82 | All animals weighed. |
| 21 Apr 82 | All surviving animals were weighed, sacrificed and gross necropsied. |

Statistical Analysis

_ight male animals were assigned to each of six dose groups by simple random sampling techniques using a program, Random, on the Data General C 330 computer.

.liss method of probit analysis was used to determine the LD₁, LD₅₀ and LD₉₅ values along with the corresponding 95% confidence limits (Table 2). The program, PRO317, was used to determine the probit curve and the lethal dose values. The probit regression line fit to the data was

 $Y = -28.39 + 12.78 \log X$

where X is the dose and Y the corresponding probit value.

Gross Pathology Summary and Interpretation of GLP Study 32-309; intranuscular LD $_{50}$ $^{\circ}$ 13-4, Tale ICR ice

The deaths of 2/o* male mice in Group 2 (400 mg/kg), 6// mice in Group 3 (500 mg/kg), 7/0 mice in Group 4 (600 mg/kg) and 3/3 mice in Group 5 (700 mg/kg) were attributed to the toxic effect of the tested compound. All of the deaths occurred between 4 minutes and 25 minutes following administration of the test compound by intramuscular injection. The average time from injection of the test compound to death by dosage group was: 20 minutes for Group 2, 8.6 minutes for Group 3, 6.7 minutes for Group 4, and 5.7 minutes for Group 5. None of the mice in Group 1 (300 mg/kg) or Group 6 (control) died prior to the scheduled termination of the study 14 days after injection of the test compound. One mouse was removed from Group 3 because of misdosing and data from that animal will not be included in this report.

Gross lesions attributable to the test compound were present in all of the groups in which deaths occurred but not in every animal. These lesions consisted of hemorrhage and/or congestion in the lung which was observed in the following dosage group frequency: 2/8 in Group 2, 5/7 in Group 3, 2/8 in Group 4, and 1/8 in Group 5. Gross hemorrhage was observed at the injection site in 3/8* in Group 2, 6/7 in Group 3, 6/8 in Group 4, and 8/8 in Group 5. With the exeception of one animal in Group 2, hemmorrhage at the injection site was only observed in animals that gied. It is likely that evidence of hemorrhage in animals surv ming for the 14 day observation period would have been cleared during that time.

Other lesions observed in mice on this study included corneal opacity in 1/7 mice in Group 3, hypopyon in 1/8 mice in Group 4, lens opacity in 1/8 in Group 5, bite wounds in 1// from Group 3 and 1/8 in Groups 4, 5, and 6, hydroraphrosis in 2/8 mice in Group 4, yellow spots on kidneys of 1/8 mice in Group 4 and distal end of tail missing in 2/8 mice in Group 6. These changes were considered to be incidental lesions that were unrelated to administration of the test compound.

In summary, the average time between intramuscular injection of the test compound and death in mice decreased with increased dosages of the material. The gross pathologic effects in addition to death that were most likely due to a single intramuscular injection of 14B-4 that were observed in male ICR mice in this study were congestion and/or hemorrhage in the lung. Hemorrhage at the injection site was commonly observed but was more likely the result of trauma than an effect of the test material.

* umber of mice affected/lumber of mice in the group.

THE RESERVE OF THE PROPERTY OF

Recropsies revealed no test compound-related lesions in male ICR mice that were killed at the termination of the study.
